Submitter: Shlomi Domkeno 318643640

My control system that I want to create is sun tracking system.

Solar panels are on top of an actuator which moves, depending on the light sensitivity (which are measured from a light sensor, which is also the input of the system) from the sun.

The more sunlight, the less the actuator has to correct itself (output).

```
In [2]: from gekko import GEKKO
import numpy as np
import matplotlib.pyplot as plt
```

Defenition of the set points

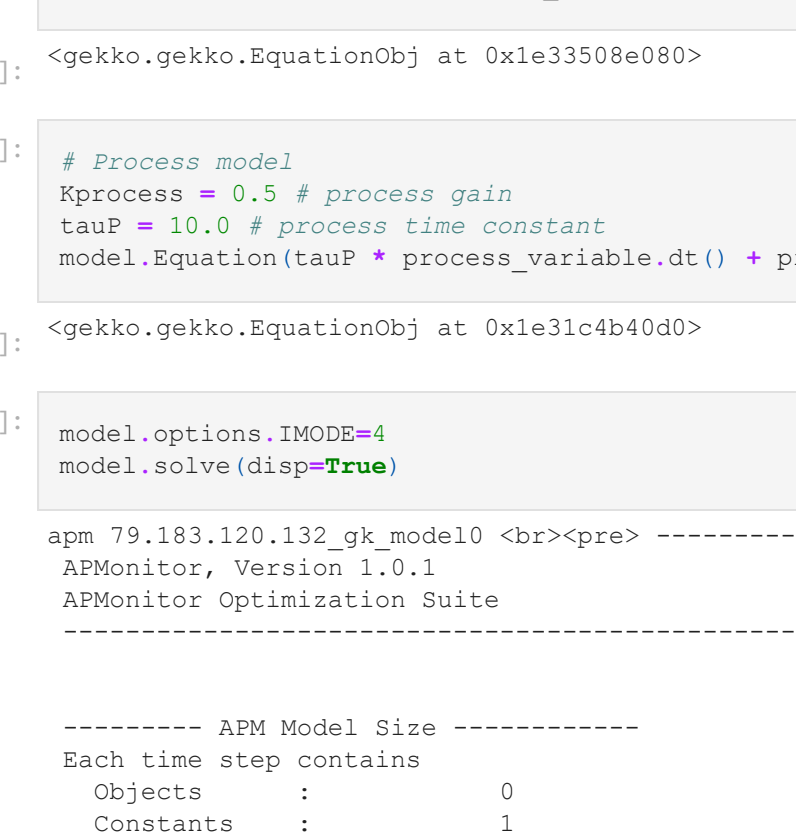

The expected output of typical day

```
In [3]: model = GEKKO()
time_steps = 24
steps = np.zeros(time_steps + 1)
steps[1:] = 50

# Steps like graph
steps[0:4] = 0
steps[4:6] = 25
steps[6:8] = 40
steps[8:10] = 50
steps[10:12] = 60
steps[12:14] = 75
steps[14:16] = 90
steps[16:18] = 0
steps[18:] = 0

# Cleaner graph
steps[14] = 0
steps[18] = 20
steps[12:14] = 50
steps[10:12] = 80
steps[16:20] = 80
steps[20:] = 0

model.time = np.linspace(0, time_steps, time_steps+1)
set_point = model.Param(value=steps)
plt.plot(model.time, set_point.value, 'k-', label='SP')
plt.show()
```

The above set points are describing:

At the beginning of the day, the sun shines from east. The actuator is pointed in the extreme east (near zero).

When the time goes by, slowly, the actuator starts pointing to the middle.

In the middle of the day, the sun is directly above the actuator, so the expected output is 50 (which is pointed north, middle of east to west).

In the night, the sun is setting in the west, so the actuator points to the extreme west (near 100).

In the middle of the night, to setup for the next day, and because the lack of sunlight, the actuator points again to the extreme east (near zero).

```

We can see that the process variable is matching the set points.

As the process variable is increasing, the output (or control) is also increasing (at the beginning, the error is big). And when the process variable is getting closer to the set points (less and less error), the PID controller saturates the control over the actuator, meaning, decrease of the output control.

If we play with the parameters Ki, Kp, Kd we get different graph, as shown below.

High Kp

```
In [9]: # Controller model
Kp = 100.0 # controller P gain
Ki = 2 # controller I gain
Kd = 1 # derivative constant
model = GEKKO()
```

```
# Steps
time_steps = 24
steps = np.zeros(time_steps + 1)
steps[1:] = 50
steps[4:] = 0
steps[4:8] = 20
steps[8:12] = 50
steps[12:16] = 80
steps[16:20] = 80
steps[20:] = 0
```

```
model.time = np.linspace(0, time_steps, time_steps+1)
set_point = model.Param(value=steps)

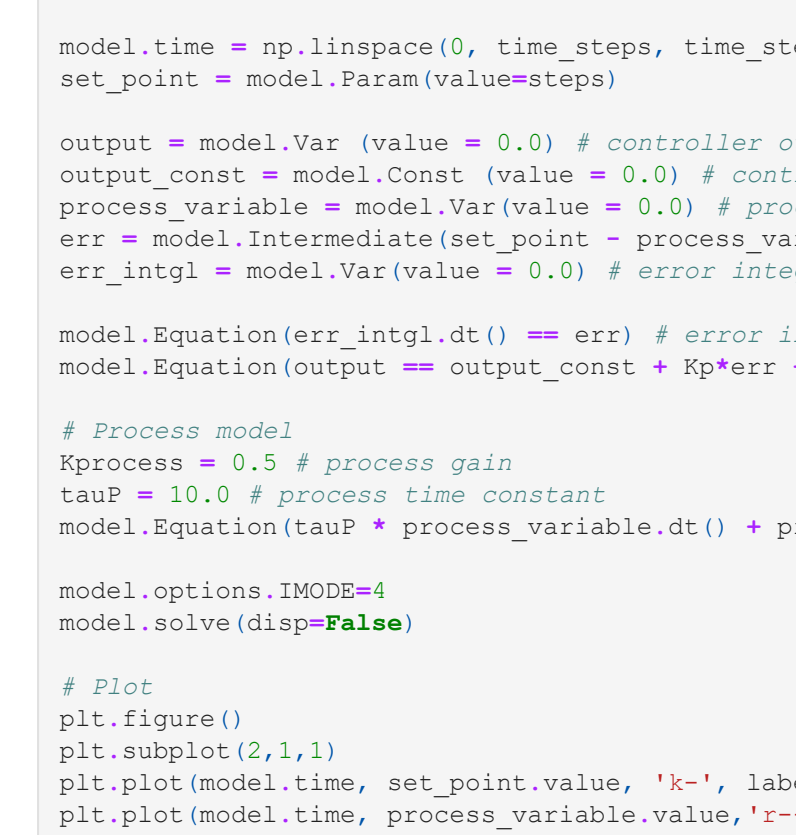

output = model.Var(value = 0.0) # controller output
output_const = model.Const(value = 0.0) # controller output bias
process_variable = model.Var(value = 0.0) # process variable
err = model.Intermediate(set_point - process_variable) # set point error
err_intgrl = model.Var(value = 0.0) # error integr
```

```
model.Equation(err_intgrl.dt() == err) # error integral
model.Equation(output == output_const + Kp*err + Ki * err_intgrl - Kd*process_variable.dt())

# Process model
Kprocess = 0.5 # process gain
tauP = 10.0 # process time constant
model.Equation(tauP * process_variable.dt() + process_variable == Kprocess*output)

model.options.IMODE=4
model.solve(disp=False)
```

```
# Plot
plt.figure()
plt.subplot(2,1,1)
plt.plot(model.time, set_point.value, 'k-', label='SP')
plt.plot(model.time, process_variable.value, 'r--', label='PV')
plt.xlabel('Time (sec)')
plt.ylabel('Process')
plt.legend()
plt.subplot(2,1,2)
plt.plot(model.time, output.value, 'b:', label='OP')
plt.plot(model.time, err_intgrl.value, 'g:', label='OP')
plt.legend()
plt.show()
```

Low Kp

```
In [10]: # Controller model
Kp = 1.0 # controller P gain
Ki = 2 # controller I gain
Kd = 1 # derivative constant
model = GEKKO()
```

```
# Steps
time_steps = 24
steps = np.zeros(time_steps + 1)
steps[1:] = 50
steps[4:] = 0
steps[4:8] = 20
steps[8:12] = 50
steps[12:16] = 80
steps[16:20] = 80
steps[20:] = 0
```

```
model.time = np.linspace(0, time_steps, time_steps+1)
set_point = model.Param(value=steps)

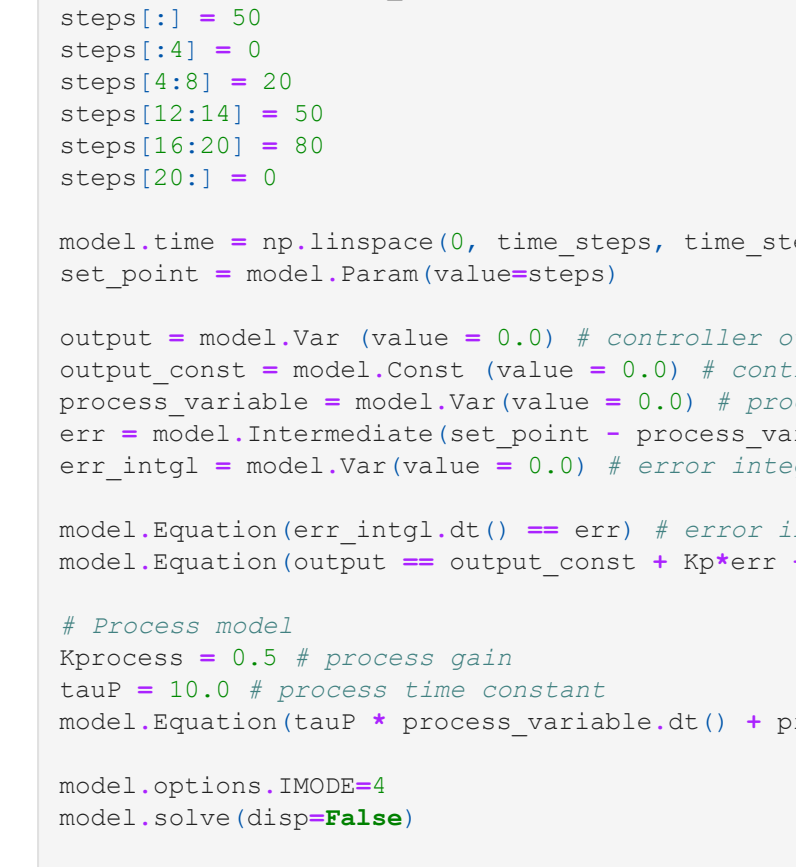

output = model.Var(value = 0.0) # controller output
output_const = model.Const(value = 0.0) # controller output bias
process_variable = model.Var(value = 0.0) # process variable
err = model.Intermediate(set_point - process_variable) # set point error
err_intgrl = model.Var(value = 0.0) # error integr
```

```
model.Equation(err_intgrl.dt() == err) # error integral
model.Equation(output == output_const + Kp*err + Ki * err_intgrl - Kd*process_variable.dt())

# Process model
Kprocess = 0.5 # process gain
tauP = 10.0 # process time constant
model.Equation(tauP * process_variable.dt() + process_variable == Kprocess*output)

model.options.IMODE=4
model.solve(disp=False)
```

```
# Plot
plt.figure()
plt.subplot(2,1,1)
plt.plot(model.time, set_point.value, 'k-', label='SP')
plt.plot(model.time, process_variable.value, 'r--', label='PV')
plt.xlabel('Time (sec)')
plt.ylabel('Process')
plt.legend()
plt.subplot(2,1,2)
plt.plot(model.time, output.value, 'b:', label='OP')
plt.plot(model.time, err_intgrl.value, 'g:', label='OP')
plt.legend()
plt.show()
```

Kp parameter experiment result

When the Kp paramter is high, as we already saw, the output is tightly coupled to the set points.

We ideally want this property.

But because of physical limitations, the actuator can't turn fast, as we can see at the time 20.00, when the pulse is to set the panels from pointing west to east.

Furthermore, we want to avoid the value of Kp to be small, as we can see in the second example. The output is almost not at all close to the set points.

The pro-protional parameter is not enough, because of this limitations. We take a look at the integral parameter next.

High Ki

```
In [11]: # Controller model
Kp = 15.0 # controller P gain
Ki = 100.0 # controller I gain
Kd = 1 # derivative constant
model = GEKKO()
```

```
# Steps
time_steps = 24
steps = np.zeros(time_steps + 1)
steps[1:] = 50
steps[4:] = 0
steps[4:8] = 20
steps[8:12] = 50
steps[12:16] = 80
steps[16:20] = 80
steps[20:] = 0
```

```
model.time = np.linspace(0, time_steps, time_steps+1)
set_point = model.Param(value=steps)

output = model.Var(value = 0.0) # controller output
output_const = model.Const(value = 0.0) # controller output bias
process_variable = model.Var(value = 0.0) # process variable
err = model.Intermediate(set_point - process_variable) # set point error
err_intgrl = model.Var(value = 0.0) # error integr
```

```
model.Equation(err_intgrl.dt() == err) # error integral
model.Equation(output == output_const + Kp*err + Ki * err_intgrl - Kd*process_variable.dt())

# Process model
Kprocess = 0.5 # process gain
tauP = 10.0 # process time constant
model.Equation(tauP * process_variable.dt() + process_variable == Kprocess*output)

model.options.IMODE=4
model.solve(disp=False)
```

```
# Plot
plt.figure()
plt.subplot(2,1,1)
plt.plot(model.time, set_point.value, 'k-', label='SP')
plt.plot(model.time, process_variable.value, 'r--', label='PV')
plt.xlabel('Time (sec)')
plt.ylabel('Process')
plt.legend()
plt.subplot(2,1,2)
plt.plot(model.time, output.value, 'b:', label='OP')
plt.plot(model.time, err_intgrl.value, 'g:', label='OP')
plt.legend()
plt.show()
```

Low Ki

As I said in the conclusion: "...we can smooth out the transition between the steady states", regarding to I controller.

We still have overshoot, which happens at the transitions. We can use Kd. We change 15 to 1.

```
